

Chapter 2 – Software Processes

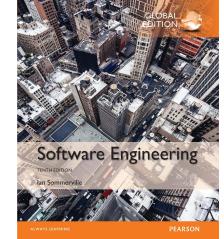

The software process

- ❖ A structured set of activities required to develop a software system.
- ❖ Many different software processes but all involve:
 - Specification – defining what the system should do;
 - Design and implementation – defining the organization of the system and implementing the system;
 - Validation – checking that it does what the customer wants;
 - Evolution – changing the system in response to changing customer needs.
- ❖ A software process model is an abstract representation of a process. It presents a description of a process from some particular perspective.

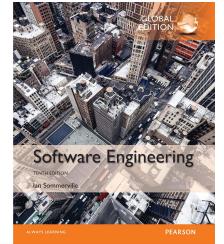

Human

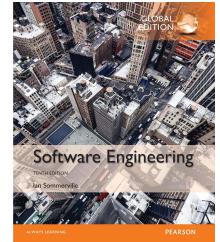

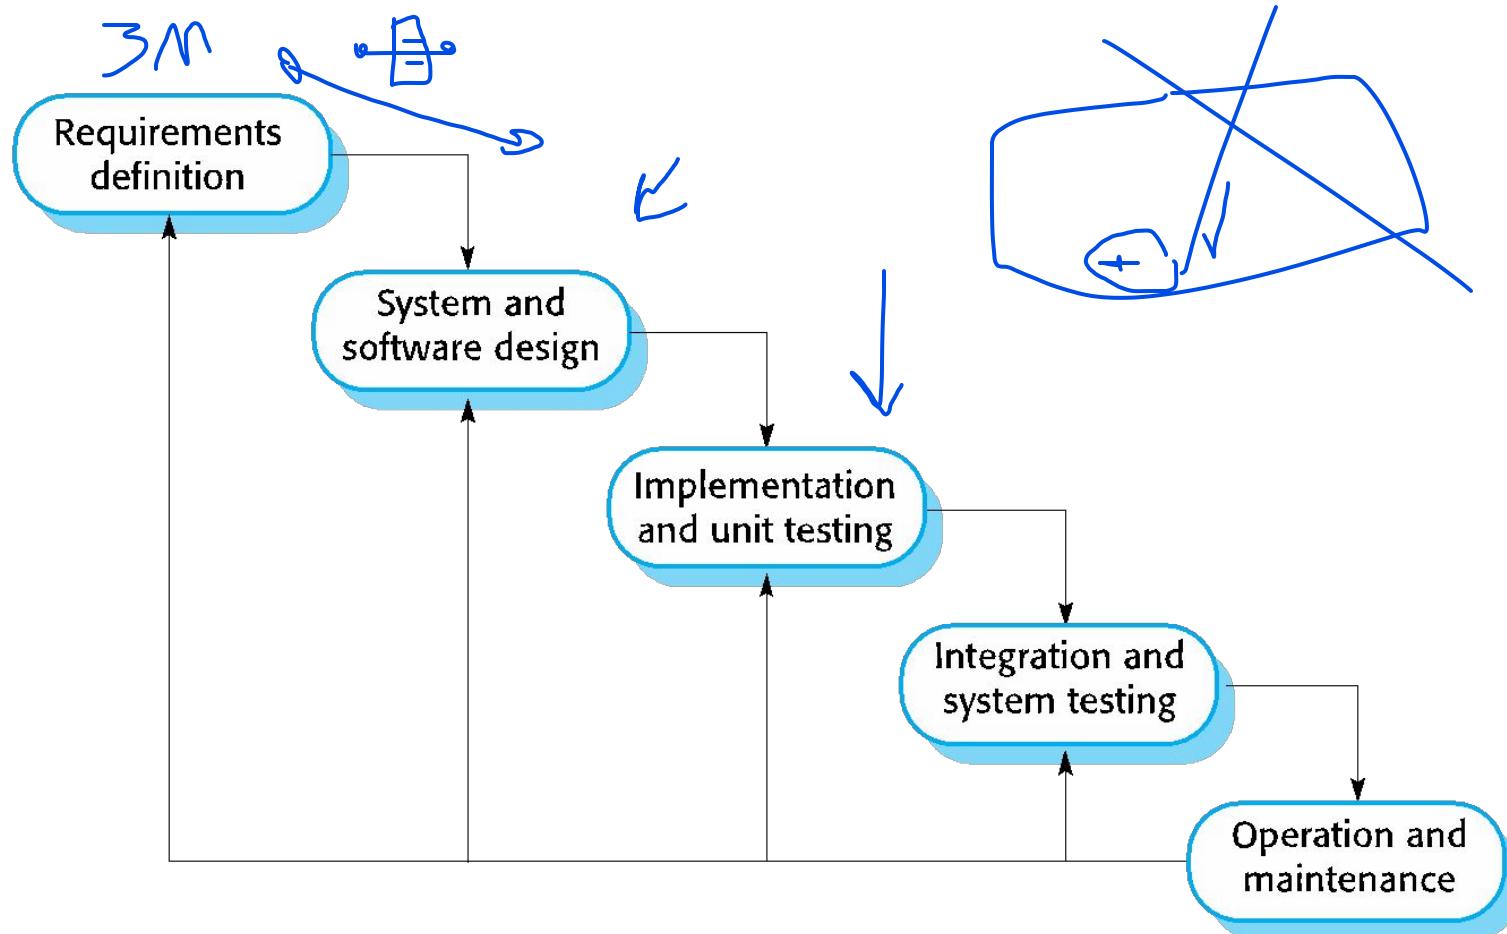

- ❖ Plan-driven processes are processes where all of the process activities are planned in advance and progress is measured against this plan.
- ❖ In agile processes, planning is incremental and it is easier to change the process to reflect changing customer requirements.
- ❖ In practice, most practical processes include elements of both plan-driven and agile approaches.
- ❖ There are no right or wrong software processes.

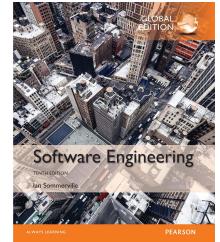

Software process models

The waterfall model

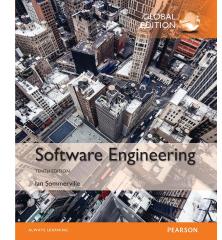

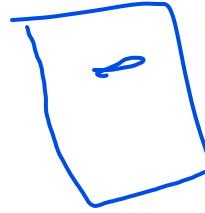

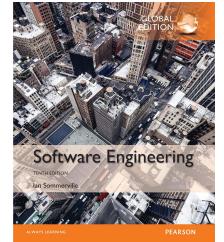

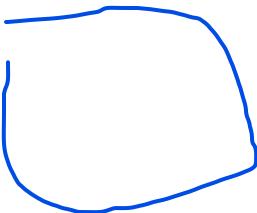

Waterfall model phases

- ❖ There are separate identified phases in the waterfall model:
 - Requirements analysis and definition
 - System and software design
 - Implementation and unit testing
 - Integration and system testing
 - Operation and maintenance
- ❖ The main drawback of the waterfall model is the difficulty of accommodating change after the process is underway. In principle, a phase has to be complete before moving onto the next phase.

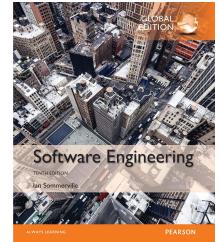

Waterfall model problems

- ❖ Inflexible partitioning of the project into distinct stages makes it difficult to respond to changing customer requirements.
 - Therefore, this model is only appropriate when the requirements are well-understood and changes will be fairly limited during the design process.
 - Few business systems have stable requirements.
- ❖ The waterfall model is mostly used for large systems engineering projects where a system is developed at several sites.
 - In those circumstances, the plan-driven nature of the waterfall model helps coordinate the work.

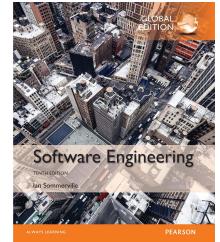

Process activities

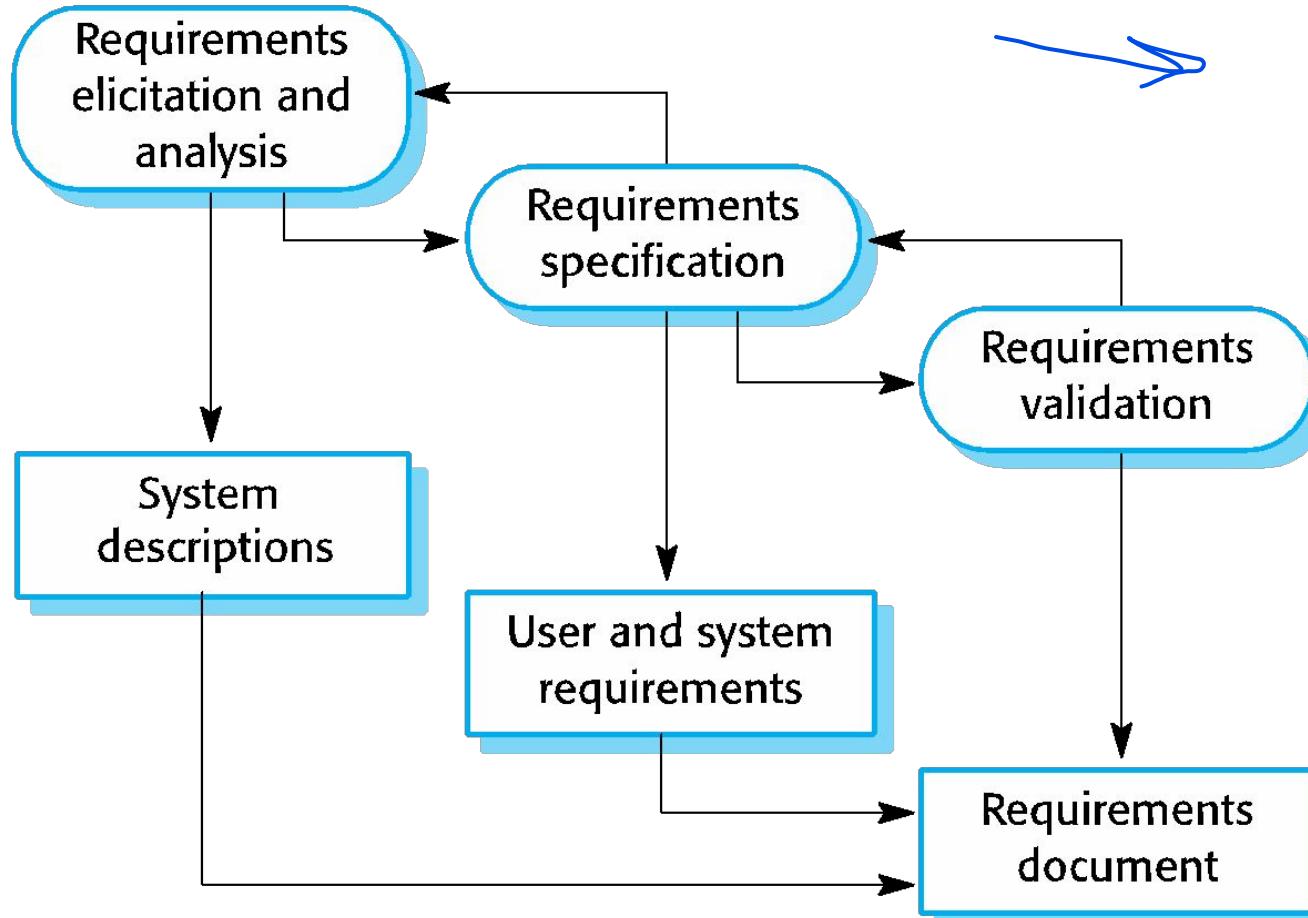

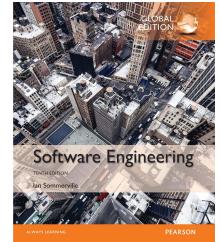

Process activities

- ❖ Real software processes are inter-leaved sequences of technical, collaborative and managerial activities with the overall goal of specifying, designing, implementing and testing a software system.
- ❖ The four basic process activities of specification, development, validation and evolution are organized differently in different development processes.
- ❖ For example, in the waterfall model, they are organized in sequence, whereas in incremental development they are interleaved.

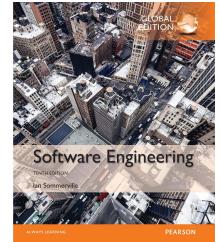

The requirements engineering process

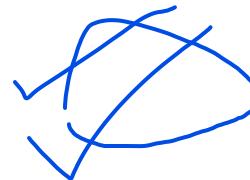

Software specification

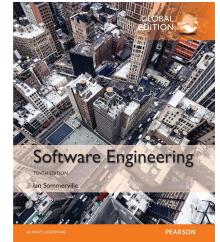

- ❖ The process of establishing what services are required and the constraints on the system's operation and development.
- ❖ Requirements engineering process
 - Requirements elicitation and analysis
 - What do the system stakeholders require or expect from the system?
 - Requirements specification
 - Defining the requirements in detail
 - Requirements validation
 - Checking the validity of the requirements

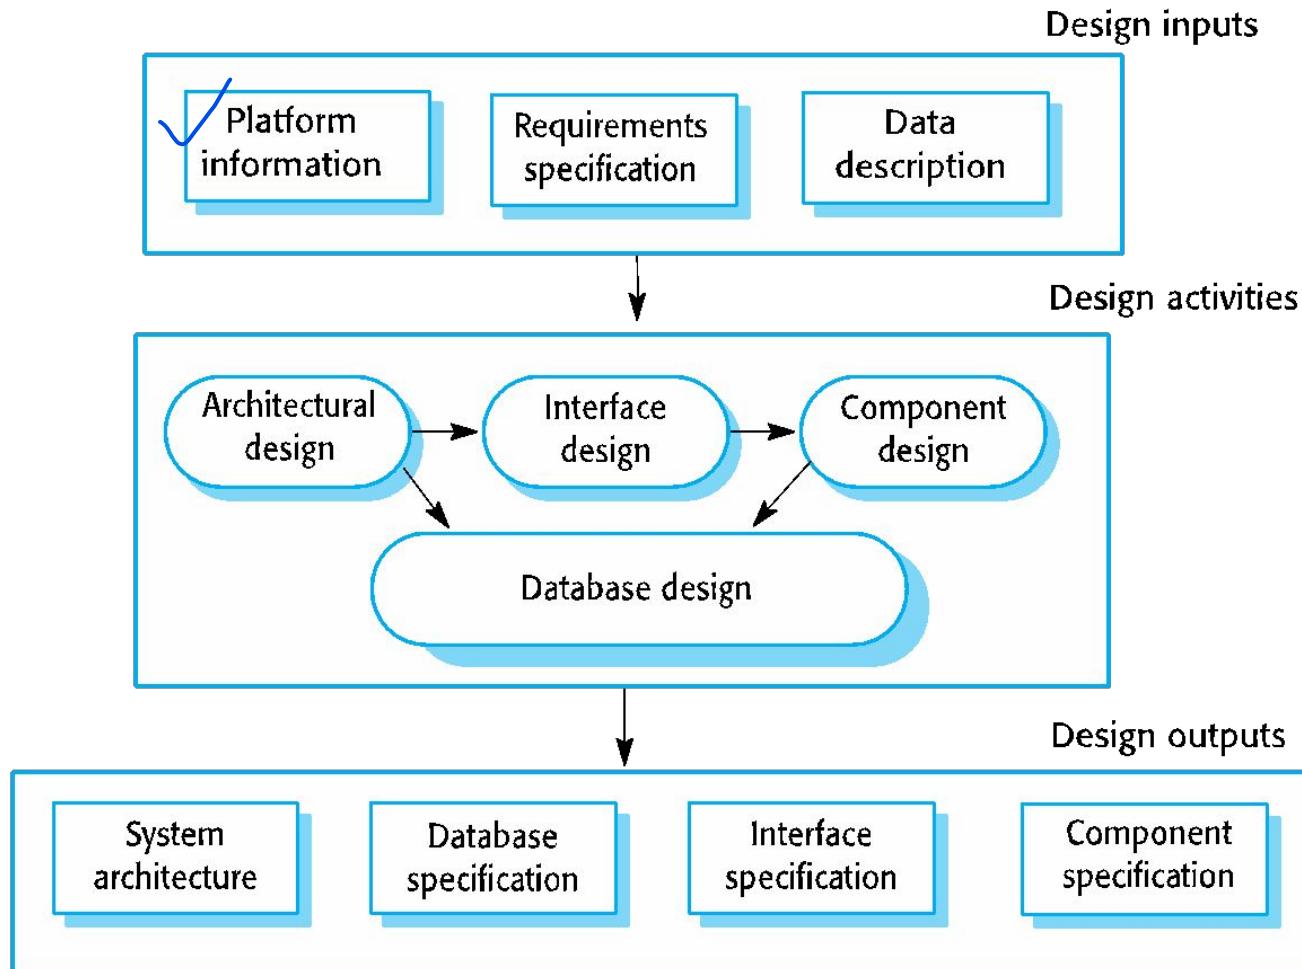

Software design and implementation

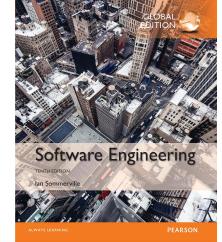

- ❖ The process of converting the system specification into an executable system.
- ❖ Software design
 - Design a software structure that realises the specification;
- ❖ Implementation
 - Translate this structure into an executable program;
- ❖ The activities of design and implementation are closely related and may be inter-leaved.

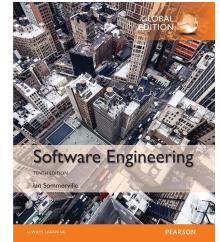

A general model of the design process

Design activities

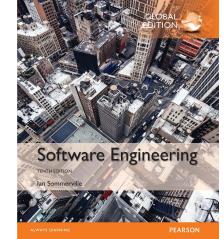

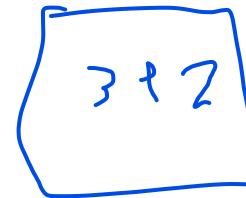

- ❖ *Architectural design*, where you identify the overall structure of the system, the principal components (subsystems or modules), their relationships and how they are distributed.
- ❖ *Database design*, where you design the system data structures and how these are to be represented in a database.
- ❖ *Interface design*, where you define the interfaces between system components.
- ❖ *Component selection and design*, where you search for reusable components. If unavailable, you design how it will operate.

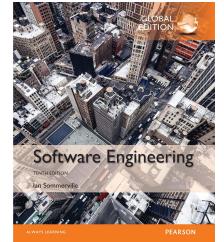

System implementation

- ❖ The software is implemented either by developing a program or programs or by configuring an application system.
- ❖ Design and implementation are interleaved activities for most types of software system.
A set of hand-drawn blue arrows on the right side of the slide. One arrow points from 'Design' down to 'Implementation'. Another arrow points from 'Implementation' back up to 'Design', forming a loop. A third arrow points from 'Implementation' to the right, suggesting further steps in the process.
- ❖ Programming is an individual activity with no standard process.
- ❖ Debugging is the activity of finding program faults and correcting these faults.

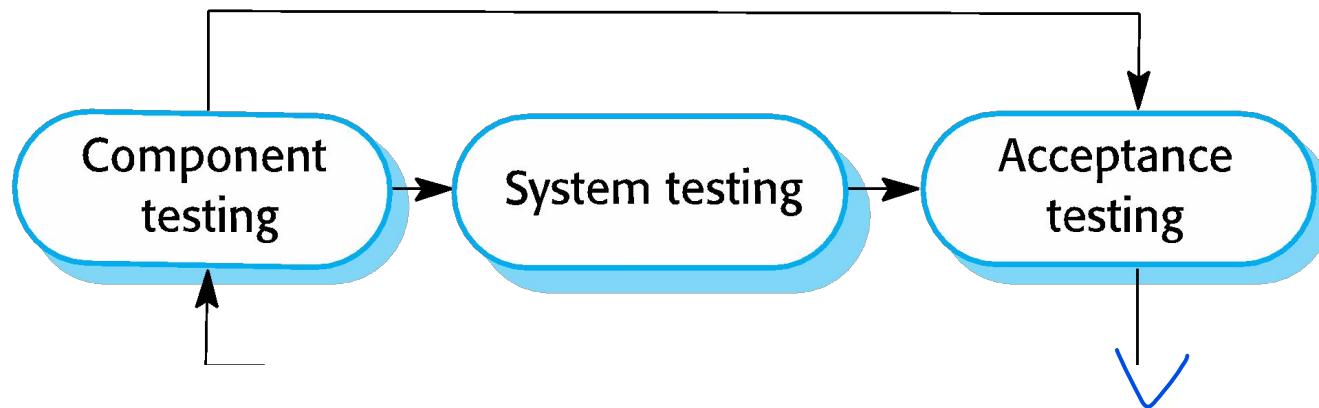

Software validation

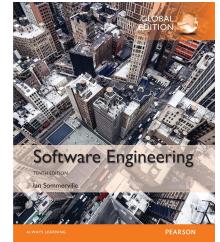

- ❖ Verification and validation (V & V) is intended to show that a system conforms to its specification and meets the requirements of the system customer.
- ❖ Involves checking and review processes and system testing.
- ❖ System testing involves executing the system with test cases that are derived from the specification of the real data to be processed by the system.
- ❖ Testing is the most commonly used V & V activity.

Stages of testing

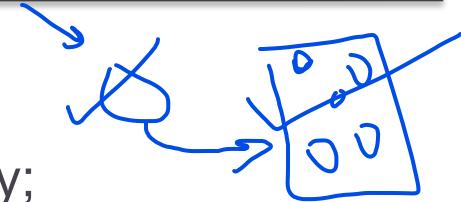

Testing stages

❖ Component testing

- Individual components are tested independently;
- Components may be functions or objects or coherent groupings of these entities.

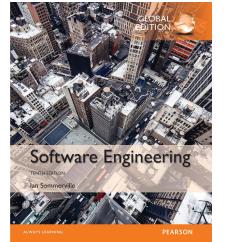

❖ System testing

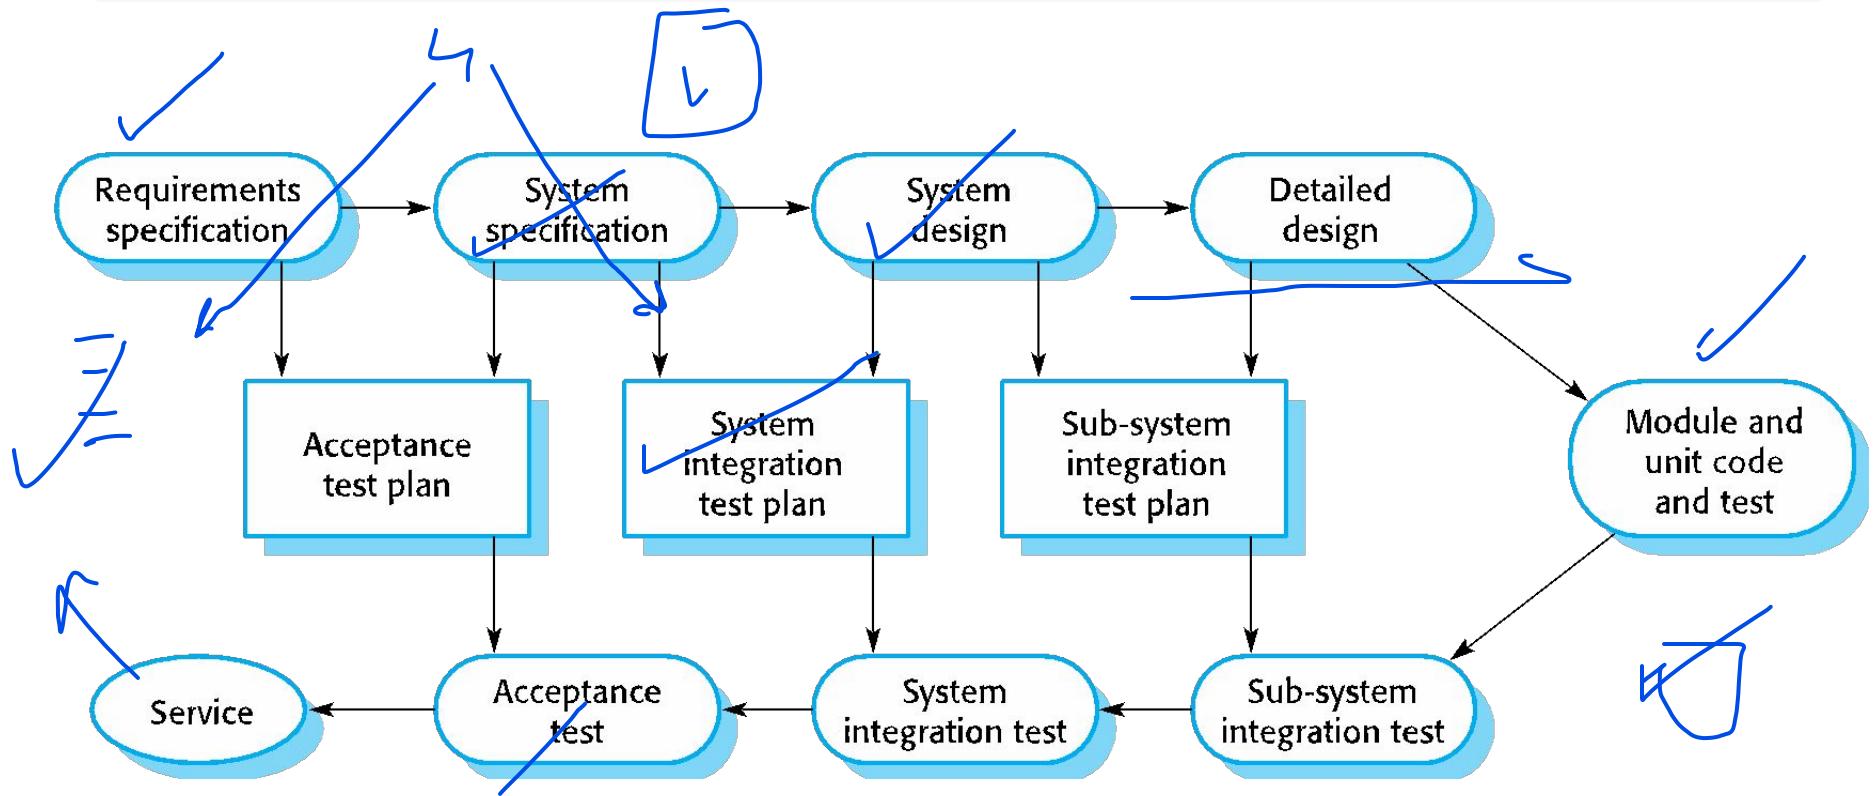

- Testing of the system as a whole. Testing of emergent properties is particularly important.

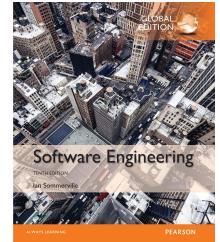

❖ Customer testing

- Testing with customer data to check that the system meets the customer's needs.

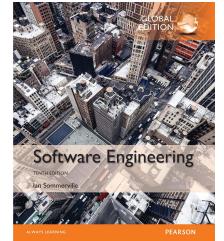

Testing phases in a plan-driven software process (V-model)

Software evolution

- ❖ Software is inherently flexible and can change.
- ❖ As requirements change through changing business circumstances, the software that supports the business must also evolve and change.
- ❖ Although there has been a demarcation between development and evolution (maintenance) this is increasingly irrelevant as fewer and fewer systems are completely new.

System evolution
